Software Engineering

Architectural Design

Objectives

- To introduce architectural design and to discuss its importance
- To explain the architectural design decisions that have to be made
- To introduce three complementary architectural styles covering organization, decomposition and control
- To discuss reference architectures are used to communicate and compare architectures
**Software architecture**

- The design process for identifying the sub-systems making up a system and the framework for sub-system control and communication is **architectural design**
- The output of this design process is a description of the **software architecture**

- **Architectural design**
  - An early stage of the system design process.
  - Represents the link between specification and design processes.
  - Often carried out in parallel with some specification activities.
  - It involves identifying major system components and their communications.

---

**Advantages of explicit architecture**

- **Stakeholder communication**
  - Architecture may be used as a focus of discussion by system stakeholders.
- **System analysis**
  - Means that analysis of whether the system can meet its non-functional requirements is possible.
- **Large-scale reuse**
  - The architecture may be reusable across a range of systems.

- **Disadvantages: architectural conflicts**
  - Using large-grain components improves performance but reduces maintainability.
  - Introducing redundant data improves availability but makes security more difficult.
  - Localizing safety-related features usually means more communication so degraded performance.
**Architecture and system characteristics**

- Performance
  - Localize critical operations and minimize communications. Use large rather than fine-grain components.
- Security
  - Use a layered architecture with critical assets in the inner layers.
- Safety
  - Localize safety-critical features in a small number of sub-systems.
- Availability
  - Include redundant components and mechanisms for fault tolerance.
- Maintainability
  - Use fine-grain, replaceable components.

**System structuring**

- Concerned with decomposing the system into interacting sub-systems.
- The architectural design is normally expressed as a block diagram presenting an overview of the system structure.
- More specific models showing how sub-systems share data, are distributed and interface with each other may also be developed.
- Box and line diagrams
  - Very abstract - they do not show the nature of component relationships nor the externally visible properties of the sub-systems.
  - However, useful for communication with stakeholders and for project planning.
**Architectural design decisions**

- Architectural design is a creative process so the process differs depending on the type of system being developed.
- However, a number of common decisions span all design processes.
  
  - Is there a generic application architecture that can be used?
  - How will the system be distributed?
  - What architectural styles are appropriate?
  - What approach will be used to structure the system?
  - How will the system be decomposed into modules?
  - What control strategy should be used?
  - How will the architectural design be evaluated?
  - How should the architecture be documented?

**Architecture reuse and style**

- Systems in the same domain often have similar architectures that reflect domain concepts.
- Application product lines are built around a core architecture with variants that satisfy particular customer requirements.

  - The architectural model of a system may conform to a generic architectural model or style.
  - An awareness of these styles can simplify the problem of defining system architectures.
  - However, most large systems are heterogeneous and do not follow a single architectural style.
**Architectural models**

- Used to document an architectural design.
- Static structural model that shows the major system components.
- Dynamic process model that shows the process structure of the system.
- Interface model that defines sub-system interfaces.
- Relationships model such as a data-flow model that shows sub-system relationships.
- Distribution model that shows how sub-systems are distributed across computers.

**System organization**

- Reflects the basic strategy that is used to structure a system.
- Three organizational styles are widely used:
  - A shared data repository style;
  - A shared services and servers style;
  - An abstract machine or layered style.
**The repository model**

- Sub-systems must exchange data. This may be done in two ways:
  - Shared data is held in a central database or repository and may be accessed by all sub-systems;
  - Each sub-system maintains its own database and passes data explicitly to other sub-systems.
- When large amounts of data are to be shared, the repository model of sharing is most commonly used.
- **Advantages**
  - Efficient way to share large amounts of data;
  - Sub-systems need not be concerned with how data is produced;
  - Centralized management e.g. backup, security, etc.
  - Sharing model is published as the repository schema.
- **Disadvantages**
  - Sub-systems must agree on a repository data model. Inevitably a compromise;
  - Data evolution is difficult and expensive;
  - No scope for specific management policies;
  - Difficult to distribute efficiently.

**Client-server model**

- Distributed system model which shows how data and processing is distributed across a range of components.
  - Set of stand-alone servers which provide specific services such as printing, data management, etc.
  - Set of clients which call on these services.
  - Network which allows clients to access servers.
- **Advantages**
  - Distribution of data is straightforward;
  - Makes effective use of networked systems. May require cheaper hardware;
  - Easy to add new servers or upgrade existing servers.
- **Disadvantages**
  - No shared data model so sub-systems use different data organization. Data interchange may be inefficient;
  - Redundant management in each server;
  - No central register of names and services - it may be hard to find out what servers and services are available.
**Abstract machine (layered) model**

- Used to model the interfacing of sub-systems.
- Organizes the system into a set of layers (or abstract machines) each of which provide a set of services.
- Supports the incremental development of sub-systems in different layers. When a layer interface changes, only the adjacent layer is affected.
- However, often artificial to structure systems in this way.

---

**Sub-systems and modules**

- A sub-system is a system in its own right whose operation is independent of the services provided by other sub-systems.
- A module is a system component that provides services to other components but would not normally be considered as a separate system.

**Modular decomposition**

- Another structural level where sub-systems are decomposed into modules.
- Two modular decomposition models covered
  - An object model where the system is decomposed into interacting object;
  - A pipeline or data-flow model where the system is decomposed into functional modules which transform inputs to outputs.
- If possible, decisions about concurrency should be delayed until modules are implemented.
**Object models**

- Structure the system into a set of loosely coupled objects with well-defined interfaces.
- Object-oriented decomposition is concerned with identifying object classes, their attributes and operations.
- When implemented, objects are created from these classes and some control model used to coordinate object operations.
- Advantages
  - Objects are loosely coupled so their implementation can be modified without affecting other objects.
  - The objects may reflect real-world entities.
  - OO implementation languages are widely used.
  - However, object interface changes may cause problems and complex entities may be hard to represent as objects.

**Function-oriented pipelining**

- Functional transformations process their inputs to produce outputs.
- May be referred to as a pipe and filter model (as in UNIX shell).
- Variants of this approach are very common. When transformations are sequential, this is a batch sequential model which is extensively used in data processing systems.
- Not really suitable for interactive systems.
- Advantages
  - Supports transformation reuse.
  - Intuitive organization for stakeholder communication.
  - Easy to add new transformations.
  - Relatively simple to implement as either a concurrent or sequential system.
  - However, requires a common format for data transfer along the pipeline and difficult to support event-based interaction.
Control styles

- Are concerned with the control flow between sub-systems. Distinct from the system decomposition model.
- Centralized control
  - One sub-system has overall responsibility for control and starts and stops other sub-systems.
- Event-based control
  - Each sub-system can respond to externally generated events from other sub-systems or the system’s environment.

Centralized control

- A control sub-system takes responsibility for managing the execution of other sub-systems.
- Call-return model
  - Top-down subroutine model where control starts at the top of a subroutine hierarchy and moves downwards. Applicable to sequential systems.
- Manager model
  - Applicable to concurrent systems. One system component controls the stopping, starting and coordination of other system processes. Can be implemented in sequential systems as a case statement.
**Event-driven systems**

- Driven by externally generated events where the timing of the event is not controlled by the sub-systems which process the event.
- Two principal event-driven models

**Broadcast models**
- Effective in integrating sub-systems on different computers in a network.
- Sub-systems register an interest in specific events. When these occur, control is transferred to the sub-system which can handle the event.
- Control policy is not embedded in the event and message handler. Sub-systems decide on events of interest to them.
- However, sub-systems don't know if or when an event will be handled.

**Interrupt-driven models**
- Used in real-time systems where fast response to an event is essential.
- There are known interrupt types with a handler defined for each type.
- Each type is associated with a memory location and a hardware switch causes transfer to its handler.
- Allows fast response but complex to program and difficult to validate.

---

**Reference architectures**

- Architectural models may be specific to some application domain.
- Two types of domain-specific model
  - Generic models which are abstractions from a number of real systems and which encapsulate the principal characteristics of these systems. Covered in Chapter 13.
  - Reference models which are more abstract, idealized model. Provide a means of information about that class of system and of comparing different architectures.
- Generic models are usually bottom-up models; Reference models are top-down models.
- Reference models are derived from a study of the application domain rather than from existing systems.
- May be used as a basis for system implementation or to compare different systems. It acts as a standard against which systems can be evaluated.
- OSI model is a layered model for communication systems.
Case reference model

- Data repository services
  - Storage and management of data items.
- Data integration services
  - Managing groups of entities.
- Task management services
  - Definition and enaction of process models.
- Messaging services
  - Tool-tool and tool-environment communication.
- User interface services
  - User interface development.

Key points

- The software architecture is the fundamental framework for structuring the system.
- Architectural design decisions include decisions on the application architecture, the distribution and the architectural styles to be used.
- Different architectural models such as a structural model, a control model and a decomposition model may be developed.
- System organizational models include repository models, client-server models and abstract machine models.
- Modular decomposition models include object models and pipelining models.
- Control models include centralized control and event-driven models.
- Reference architectures may be used to communicate domain-specific architectures and to assess and compare architectural designs.
