Software Engineering

Requirements Engineering

Requirements engineering

- The process of establishing the services that the customer requires from a system and the constraints under which it operates and is developed.
- The requirements themselves are the descriptions of the system services and constraints that are generated during the requirements engineering process.
What is a requirement?

✧ It may range from a high-level abstract statement of a service or of a system constraint to a detailed mathematical functional specification.

✧ This is inevitable as requirements may serve a dual function
  ▪ May be the basis for a bid for a contract - therefore must be open to interpretation;
  ▪ May be the basis for the contract itself - therefore must be defined in detail;
  ▪ Both these statements may be called requirements.

Types of requirement

✧ User requirements
  ▪ Statements in natural language plus diagrams of the services the system provides and its operational constraints. Written for customers.

✧ System requirements
  ▪ A structured document setting out detailed descriptions of the system's functions, services and operational constraints. Defines what should be implemented so may be part of a contract between client and contractor.
Readers of different types of requirements specification

User requirements
- Client managers
- System end-users
- Client engineers
- Contractor managers
- System architects

System requirements
- System end-users
- Client engineers
- System architects
- Software developers

Functional and non-functional requirements

✧ Functional requirements
  - Statements of services the system should provide, how the system should react to particular inputs and how the system should behave in particular situations.
  - May state what the system should not do.

✧ Non-functional requirements
  - Constraints on the services or functions offered by the system such as timing constraints, constraints on the development process, standards, etc.
  - Often apply to the system as a whole rather than individual features or services.

✧ Domain requirements
  - Constraints on the system from the domain of operation
**Functional requirements**

- Describe functionality or system services.
- Depend on the type of software, expected users and the type of system where the software is used.
- Functional user requirements may be high-level statements of what the system should do.
- Functional system requirements should describe the system services in detail.

**Requirements imprecision**

- Problems arise when requirements are not precisely stated.
- Ambiguous requirements may be interpreted in different ways by developers and users.
Requirements completeness and consistency

✧ In principle, requirements should be both complete and consistent.
✧ Complete
  ● They should include descriptions of all facilities required.
✧ Consistent
  ● There should be no conflicts or contradictions in the descriptions of the system facilities.
✧ In practice, it is impossible to produce a complete and consistent requirements document.

Non-functional requirements

✧ These define system properties and constraints e.g. reliability, response time and storage requirements. Constraints are I/O device capability, system representations, etc.
✧ Process requirements may also be specified mandating a particular IDE, programming language or development method.
✧ Non-functional requirements may be more critical than functional requirements. If these are not met, the system may be useless.
Types of nonfunctional requirement

Non-functional requirements implementation

- Non-functional requirements may affect the overall architecture of a system rather than the individual components.
  - For example, to ensure that performance requirements are met, you may have to organize the system to minimize communications between components.
- A single non-functional requirement, such as a security requirement, may generate a number of related functional requirements that define system services that are required.
  - It may also generate requirements that restrict existing requirements.
Non-functional classifications

✧ Product requirements
  ▪ Requirements which specify that the delivered product must behave in a particular way e.g. execution speed, reliability, etc.

✧ Organisational requirements
  ▪ Requirements which are a consequence of organisational policies and procedures e.g. process standards used, implementation requirements, etc.

✧ External requirements
  ▪ Requirements which arise from factors which are external to the system and its development process e.g. interoperability requirements, legislative requirements, etc.

Goals and requirements

✧ Non-functional requirements may be very difficult to state precisely and imprecise requirements may be difficult to verify.

✧ Goal
  ▪ A general intention of the user such as ease of use.

✧ Verifiable non-functional requirement
  ▪ A statement using some measure that can be objectively tested.

✧ Goals are helpful to developers as they convey the intentions of the system users.
Usability requirements

❖ The system should be easy to use by medical staff and should be organized in such a way that user errors are minimized. (Goal)
❖ Medical staff shall be able to use all the system functions after four hours of training. After this training, the average number of errors made by experienced users shall not exceed two per hour of system use. (Testable non-functional requirement)

Metrics for specifying nonfunctional requirements

Domain requirements

- The system’s operational domain imposes requirements on the system.
  - For example, a train control system has to take into account the braking characteristics in different weather conditions.
- Domain requirements be new functional requirements, constraints on existing requirements or define specific computations.
- If domain requirements are not satisfied, the system may be unworkable.

Domain requirements problems

- Understandability
  - Requirements are expressed in the language of the application domain;
  - This is often not understood by software engineers developing the system.
- Implicitness
  - Domain specialists understand the area so well that they do not think of making the domain requirements explicit.
The software requirements document

- The software requirements document is the official statement of what is required of the system developers.
- Should include both a definition of user requirements and a specification of the system requirements.
- It is NOT a design document. As far as possible, it should set of WHAT the system should do rather than HOW it should do it.

Users of a requirements document

- System customers: Specify the requirements and read them to check that they meet their needs. Customers specify changes to the requirements.
- Managers: Use the requirements document to plan a bid for the system and to plan the system development process.
- System engineers: Use the requirements to understand what system is to be developed.
- System test engineers: Use the requirements to develop validation tests for the system.
- System maintenance engineers: Use the requirements to understand the system and the relationships between its parts.
Requirements document variability

✧ Information in requirements document depends on type of system and the approach to development used.
✧ Systems developed incrementally will, typically, have less detail in the requirements document.
✧ Requirements documents standards have been designed e.g. IEEE standard. These are mostly applicable to the requirements for large systems engineering projects.

The structure of a requirements document

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Preface</td>
<td>This should define the expected readership of the document and describe its version history, including a rationale for the creation of a new version and a summary of the changes made in each version.</td>
</tr>
<tr>
<td>Introduction</td>
<td>This should describe the need for the system. It should briefly describe the system’s functions and explain how it will work with other systems. It should also describe how the system fits into the overall business or strategic objectives of the organization commissioning the software.</td>
</tr>
<tr>
<td>Glossary</td>
<td>This should define the technical terms used in the document. You should not make assumptions about the experience or expertise of the reader.</td>
</tr>
<tr>
<td>User requirements definition</td>
<td>Here, you describe the services provided for the user. The nonfunctional system requirements should also be described in this section. This description may use natural language, diagrams, or other notations that are understandable to customers. Product and process standards that must be followed should be specified.</td>
</tr>
<tr>
<td>System architecture</td>
<td>This chapter should present a high-level overview of the anticipated system architecture, showing the distribution of functions across system modules. Architectural components that are reused should be highlighted.</td>
</tr>
</tbody>
</table>
The structure of a requirements document

<table>
<thead>
<tr>
<th>Chapter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>System requirements specification</td>
<td>This should describe the functional and nonfunctional requirements in more detail. If necessary, further detail may also be added to the nonfunctional requirements. Interfaces to other systems may be defined.</td>
</tr>
<tr>
<td>System models</td>
<td>This might include graphical system models showing the relationships between the system components and the system and its environment. Examples of possible models are object models, data-flow models, or semantic data models.</td>
</tr>
<tr>
<td>System evolution</td>
<td>This should describe the fundamental assumptions on which the system is based, and any anticipated changes due to hardware evolution, changing user needs, and so on. This section is useful for system designers as it may help them avoid design decisions that would constrain likely future changes to the system.</td>
</tr>
<tr>
<td>Appendices</td>
<td>These should provide detailed, specific information that is related to the application being developed; for example, hardware and database descriptions. Hardware requirements define the minimal and optimal configurations for the system. Database requirements define the logical organization of the data used by the system and the relationships between data.</td>
</tr>
<tr>
<td>Index</td>
<td>Several indexes to the document may be included. As well as a normal alphabetic index, there may be an index of diagrams, an index of functions, and so on.</td>
</tr>
</tbody>
</table>

Requirements specification

✧ The process of writing down the user and system requirements in a requirements document.

✧ User requirements have to be understandable by end-users and customers who do not have a technical background.

✧ System requirements are more detailed requirements and may include more technical information.

✧ The requirements may be part of a contract for the system development
  ▪ It is therefore important that these are as complete as possible.
Ways of writing a system requirements specification

<table>
<thead>
<tr>
<th>Notation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Natural language</td>
<td>The requirements are written using numbered sentences in natural language. Each sentence should express one requirement.</td>
</tr>
<tr>
<td>Structured natural language</td>
<td>The requirements are written in natural language on a standard form or template. Each field provides information about an aspect of the requirement.</td>
</tr>
<tr>
<td>Design description languages</td>
<td>This approach uses a language like a programming language, but with more abstract features to specify the requirements by defining an operational model of the system. This approach is now rarely used although it can be useful for interface specifications.</td>
</tr>
<tr>
<td>Graphical notations</td>
<td>Graphical models, supplemented by text annotations, are used to define the functional requirements for the system; UML use case and sequence diagrams are commonly used.</td>
</tr>
<tr>
<td>Mathematical specifications</td>
<td>These notations are based on mathematical concepts such as finite-state machines or sets. Although these unambiguous specifications can reduce the ambiguity in a requirements document, most customers don’t understand a formal specification. They cannot check that it represents what they want and are reluctant to accept it as a system contract.</td>
</tr>
</tbody>
</table>

Requirements and design

- In principle, requirements should state what the system should do and the design should describe how it does this.
- In practice, requirements and design are inseparable
  - A system architecture may be designed to structure the requirements;
  - The system may inter-operate with other systems that generate design requirements;
  - The use of a specific architecture to satisfy non-functional requirements may be a domain requirement.
  - This may be the consequence of a regulatory requirement.
Natural language specification

✧ Requirements are written as natural language sentences supplemented by diagrams and tables.
✧ Used for writing requirements because it is expressive, intuitive and universal. This means that the requirements can be understood by users and customers.

Guidelines for writing requirements

✧ Invent a standard format and use it for all requirements.
✧ Use language in a consistent way. Use shall for mandatory requirements, should for desirable requirements.
✧ Use text highlighting to identify key parts of the requirement.
✧ Avoid the use of computer jargon.
✧ Include an explanation (rationale) of why a requirement is necessary.
Problems with natural language

- Lack of clarity
  - Precision is difficult without making the document difficult to read.
- Requirements confusion
  - Functional and non-functional requirements tend to be mixed-up.
- Requirements amalgamation
  - Several different requirements may be expressed together.

Structured specifications

- An approach to writing requirements where the freedom of the requirements writer is limited and requirements are written in a standard way.
- This works well for some types of requirements e.g. requirements for embedded control system but is sometimes too rigid for writing business system requirements.
Form-based specifications

✧ Definition of the function or entity.
✧ Description of inputs and where they come from.
✧ Description of outputs and where they go to.
✧ Information about the information needed for the computation and other entities used.
✧ Description of the action to be taken.
✧ Pre and post conditions (if appropriate).
✧ The side effects (if any) of the function.

Tabular specification

✧ Used to supplement natural language.
✧ Particularly useful when you have to define a number of possible alternative courses of action.
✧ For example, the insulin pump systems bases its computations on the rate of change of blood sugar level and the tabular specification explains how to calculate the insulin requirement for different scenarios.
Requirements engineering processes

✧ The processes used for RE vary widely depending on the application domain, the people involved and the organisation developing the requirements.

✧ However, there are a number of generic activities common to all processes
  ▪ Requirements elicitation;
  ▪ Requirements analysis;
  ▪ Requirements validation;
  ▪ Requirements management.

✧ In practice, RE is an iterative activity in which these processes are interleaved.

A spiral view of the requirements engineering process
Requirements elicitation and analysis

✧ Sometimes called requirements elicitation or requirements discovery.
✧ Involves technical staff working with customers to find out about the application domain, the services that the system should provide and the system’s operational constraints.
✧ May involve end-users, managers, engineers involved in maintenance, domain experts, trade unions, etc. These are called stakeholders.

Problems of requirements analysis

✧ Stakeholders don’t know what they really want.
✧ Stakeholders express requirements in their own terms.
✧ Different stakeholders may have conflicting requirements.
✧ Organisational and political factors may influence the system requirements.
✧ The requirements change during the analysis process. New stakeholders may emerge and the business environment may change.
Requirements elicitation and analysis

✧ Software engineers work with a range of system stakeholders to find out about the application domain, the services that the system should provide, the required system performance, hardware constraints, other systems, etc.

✧ Stages include:
  ▪ Requirements discovery,
  ▪ Requirements classification and organization,
  ▪ Requirements prioritization and negotiation,
  ▪ Requirements specification.

Process activities

✧ Requirements discovery
  ▪ Interacting with stakeholders to discover their requirements. Domain requirements are also discovered at this stage.

✧ Requirements classification and organisation
  ▪ Groups related requirements and organises them into coherent clusters.

✧ Prioritisation and negotiation
  ▪ Prioritising requirements and resolving requirements conflicts.

✧ Requirements specification
  ▪ Requirements are documented and input into the next round of the spiral.
Problems of requirements elicitation

✧ Stakeholders don’t know what they really want.
✧ Stakeholders express requirements in their own terms.
✧ Different stakeholders may have conflicting requirements.
✧ Organisational and political factors may influence the system requirements.
✧ The requirements change during the analysis process. New stakeholders may emerge and the business environment change.

Requirements discovery

✧ The process of gathering information about the required and existing systems and distilling the user and system requirements from this information.
✧ Interaction is with system stakeholders from managers to external regulators.
✧ Systems normally have a range of stakeholders.
Interviewing

- Formal or informal interviews with stakeholders are part of most RE processes.
- Types of interview
  - Closed interviews based on pre-determined list of questions
  - Open interviews where various issues are explored with stakeholders.
- Effective interviewing
  - Be open-minded, avoid pre-conceived ideas about the requirements and are willing to listen to stakeholders.
  - Prompt the interviewee to get discussions going using a springboard question, a requirements proposal, or by working together on a prototype system.

Interviews in practice

- Normally a mix of closed and open-ended interviewing.
- Interviews are good for getting an overall understanding of what stakeholders do and how they might interact with the system.
- Interviews are not good for understanding domain requirements
  - Requirements engineers cannot understand specific domain terminology;
  - Some domain knowledge is so familiar that people find it hard to articulate or think that it isn’t worth articulating.
Scenarios

✧ Scenarios are real-life examples of how a system can be used.
✧ They should include
  ▪ A description of the starting situation;
  ▪ A description of the normal flow of events;
  ▪ A description of what can go wrong;
  ▪ Information about other concurrent activities;
  ▪ A description of the state when the scenario finishes.

Use cases

✧ Use-cases are a scenario based technique in the UML which identify the actors in an interaction and which describe the interaction itself.
✧ A set of use cases should describe all possible interactions with the system.
✧ High-level graphical model supplemented by more detailed tabular description (see Chapter 5).
✧ Sequence diagrams may be used to add detail to use-cases by showing the sequence of event processing in the system.
Ethnography

- A social scientist spends a considerable time observing and analysing how people actually work.
- People do not have to explain or articulate their work.
- Social and organisational factors of importance may be observed.
- Ethnographic studies have shown that work is usually richer and more complex than suggested by simple system models.

Scope of ethnography

- Requirements that are derived from the way that people actually work rather than the way in which process definitions suggest that they ought to work.
- Requirements that are derived from cooperation and awareness of other people’s activities.
  - Awareness of what other people are doing leads to changes in the ways in which we do things.
- Ethnography is effective for understanding existing processes but cannot identify new features that should be added to a system.
Focused ethnography

- Developed in a project studying the air traffic control process
- Combines ethnography with prototyping
- Prototype development results in unanswered questions which focus the ethnographic analysis.
- The problem with ethnography is that it studies existing practices which may have some historical basis which is no longer relevant.

Ethnography and prototyping for requirements analysis

- Ethnographic analysis
- Debriefing meetings
- Focused ethnography
- Prototype evaluation
- System prototyping
- Generic system development
Requirements validation

✧ Concerned with demonstrating that the requirements define the system that the customer really wants.
✧ Requirements error costs are high so validation is very important
  ■ Fixing a requirements error after delivery may cost up to 100 times the cost of fixing an implementation error.

Requirements checking

✧ Validity. Does the system provide the functions which best support the customer’s needs?
✧ Consistency. Are there any requirements conflicts?
✧ Completeness. Are all functions required by the customer included?
✧ Realism. Can the requirements be implemented given available budget and technology
✧ Verifiability. Can the requirements be checked?
Requirements validation techniques

✧ Requirements reviews
  - Systematic manual analysis of the requirements.

✧ Prototyping
  - Using an executable model of the system to check requirements.
    Covered in Chapter 2.

✧ Test-case generation
  - Developing tests for requirements to check testability.

Requirements reviews

✧ Regular reviews should be held while the requirements definition is being formulated.

✧ Both client and contractor staff should be involved in reviews.

✧ Reviews may be formal (with completed documents) or informal. Good communications between developers, customers and users can resolve problems at an early stage.
Review checks

✧ Verifiability
  - Is the requirement realistically testable?

✧ Comprehensibility
  - Is the requirement properly understood?

✧ Traceability
  - Is the origin of the requirement clearly stated?

✧ Adaptability
  - Can the requirement be changed without a large impact on other requirements?

Requirements management

✧ Requirements management is the process of managing changing requirements during the requirements engineering process and system development.

✧ New requirements emerge as a system is being developed and after it has gone into use.

✧ You need to keep track of individual requirements and maintain links between dependent requirements so that you can assess the impact of requirements changes. You need to establish a formal process for making change proposals and linking these to system requirements.
Changing requirements

✧ The business and technical environment of the system always changes after installation.
  ▪ New hardware may be introduced, it may be necessary to interface the system with other systems, business priorities may change (with consequent changes in the system support required), and new legislation and regulations may be introduced that the system must necessarily abide by.

✧ The people who pay for a system and the users of that system are rarely the same people.
  ▪ System customers impose requirements because of organizational and budgetary constraints. These may conflict with end-user requirements and, after delivery, new features may have to be added for user support if the system is to meet its goals.

Changing requirements

✧ Large systems usually have a diverse user community, with many users having different requirements and priorities that may be conflicting or contradictory.
  ▪ The final system requirements are inevitably a compromise between them and, with experience, it is often discovered that the balance of support given to different users has to be changed.
Requirements evolution

- Initial understanding of problem
- Changed understanding of problem
- Initial requirements
- Changed requirements

Time

Requirements management planning

- Establishes the level of requirements management detail that is required.
- Requirements management decisions:
  - **Requirements identification** Each requirement must be uniquely identified so that it can be cross-referenced with other requirements.
  - **A change management process** This is the set of activities that assess the impact and cost of changes. I discuss this process in more detail in the following section.
  - **Traceability policies** These policies define the relationships between each requirement and between the requirements and the system design that should be recorded.
  - **Tool support** Tools that may be used range from specialist requirements management systems to spreadsheets and simple database systems.
Requirements change management

✧ Deciding if a requirements change should be accepted

  ▪ **Problem analysis and change specification**
    • During this stage, the problem or the change proposal is analyzed to check that it is valid. This analysis is fed back to the change requestor who may respond with a more specific requirements change proposal, or decide to withdraw the request.
  
  ▪ **Change analysis and costing**
    • The effect of the proposed change is assessed using traceability information and general knowledge of the system requirements. Once this analysis is completed, a decision is made whether or not to proceed with the requirements change.

  ▪ **Change implementation**
    • The requirements document and, where necessary, the system design and implementation, are modified. Ideally, the document should be organized so that changes can be easily implemented.
